Chapter 5

Constants, tuples, and types

5.1 Literals and basic types

All programs rely on processing of data, and an essential property of data is its type. A literal is a fixed value such as "3", and if we type the number 3 in an interactive session at the input prompt, then F# responds as follows,

 \cdot type \cdot literal

```
> 3;;
val it : int = 3
```

Listing 5.1: fsharpi, Typing the number 3.

What this means is that F# has inferred the type to be *int* and bound it to the identifier it. Rumor has it, that the identifier it is an abbreviation for 'irrelevant'. For more on binding and identifiers see Chapter 6. Types matter, since the operations that can be performed on integers are quite different from those that can be performed on, e.g., strings. I.e.,

·int ·it

```
> 3;;
val it : int = 3
> 3.0;;
val it : float = 3.0
> '3';;
val it : char = '3'
> "3";;
val it : string = "3"
```

Listing 5.2: fsharpi, Many representations of the number 3 but using different types.

Each literal represent the number 3, but their types are different, and hence they are quite different values. The types int for integer numbers, float for floating point numbers, char for characters, and string for strings of characters are the most common types of literals. A table of all *basic types* predefined in F# is given in Table 5.1. Besides these built-in types, F# is designed such that it is easy to define new types.

Humans like to use the decimal number system for representing numbers. Decimal numbers are base 10 means that for a number consisting of a sequence of digits separated by a decimal point, where each digit can have values $d \in \{0, 1, 2, ..., 9\}$, and the value, which each digit represents is proportional to its position. The part befor the decimal point is called the whole part and the part after is called the fractional part of the number. The whole part without a decimal point and a fractional part is called an integer number. As an example 35.7 is a decimal number, whose value is $3 \cdot 10^1 + 5 \cdot 10^0 + 7 \cdot 10^{-1}$. In F# a decimal number is called a floating point number and in this text we use Extended Backus-Naur Form (EBNF) to describe the grammar of F#, the decimal number just described is given as,

```
dDigit = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9" dInt = dDigit {dDigit}
```

 \cdot basic types

- $\cdot \ decimal \ number$
- \cdot base

- · digit
- · whole part
- · fractional part
- · integer number
- · floating point number
- · Extended Backus-Naur Form
- · EBNF

Metatype	Type name	Description
Boolean	bool	Boolean values true or false
Integer	int	Integer values from -2,147,483,648 to 2,147,483,647
	byte	Integer values from 0 to 255
	sbyte	Integer values from -128 to 127
	int8	Synonymous with byte
	uint8	Synonymous with sbyte
	int16	Integer values from -32768 to 32767
	uint16	Integer values from 0 to 65535
	int32	Synonymous with int
	uint32	Integer values from 0 to 4,294,967,295
	int64	Integer values from -9,223,372,036,854,775,808 to
		9,223,372,036,854,775,807
	uint64	Integer values from 0 to 18,446,744,073,709,551,615
	nativeint	A native pointer as a signed integer
	unativeint	A native pointer as an unsigned integer
		64-bit IEEE 754 floating point value from $-\infty$ to ∞
	double	Synonymous with float
	single	A 32-bit floating point type
	float32	Synonymous with single
	decimal	A floating point data type that has at least 28 significant digits
Character	char	Unicode character
	string	Unicode sequence of characters
None	\mathbf{unit}	No value denoted
Object	obj	An object
Exception	exn	An exception

Table 5.1: List of basic types. The most commonly used types are highlighted in bold. For at description of integer see Appendix A.1, for floating point numbers see Appendix A.2, for ASCII and Unicode characters see Appendix B, for objects see Chapter 18, and for exceptions see Chapter 11.

```
dFloat = dInt "." {dDigit}
```

meaning that a dDigit is either "0" or "1" or ... or "9", an dInt is 1 or more dDigit, and a dFloat is 1 or more digits, a dot and 0 or more digits. There is no space between the digits and between digits and the dot. So 3, 049 are examples of integers, 34.89 3. are examples of floats, while .5 is neither. Floating point numbers may alternatively be given using *scientific notation*, such as 3.5e-4 and 4e2, which means the number $3.5 \cdot 10^{-4} = 0.00035$ and $4 \cdot 10^2 = 400$. To describe this in EBNF we write

 \cdot scientific notation

```
sFloat = (dInt | dFloat) ("e" | "E" ) ["+" | "-"] dInt
float = dFloat | sFloat
```

Note that the number before the token e may be an dInt or a dFloat, but the exponent value must be an dInt.

The basic unit of information in almost all computers is the binary digit or bit for short. A binary number consists of a sequence of binary digits separated by a decimal point, where each digit can have values $b \in \{0,1\}$, and the base is 2. E.g., the binary number $101.01_2 = 1 \cdot 2^2 + 0 \cdot 2^1 + 1 \cdot 2^0 + 0 \cdot 2^{-1} + 1 \cdot 2^1 = 5.25$. Binary numbers are closely related to octal and hexadecimal numbers, where octals uses 8 as basis and can be written in binary using 3 bits, while hexadecimal numbers uses 16 as basis and can be written in binary using 4 bits. Octals and hexadecimals thus conveniently serve as shorthand for the much longer binary representation. F# has a syntax for writing integers on binary, octal, decimal, and hexadecimal numbers as,

```
bDigit = "0" | "1"

oDigit = bDigit | "2" | "3" | "4" | "5" | "6" | "7"

dDigit = oDigit | "8" | "9"

xDigit =

dDigit

| "A" | "B" | "C" | "D" | "E" | "F"

| "a" | "b" | "c" | "d" | "e" | "f"

dInt = dDigit {dDigit}

bitInt = "0" ("b" | "B") bDigit {bDigit}

octInt = "0" ("o" | "0") oDigit {oDigit}

hexInt = "0" ("x" | "X") xDigit {xDigit}

xInt = bitInt | octInt | hexInt

int = dInt | xInt
```

For example 367 is an dInt, 0b101101111, 0o557, and 0x16f is a bitInt, octInt, and hexInt, i.e., a binary, an octal, and a hexadecimal number, they are examples of an xInt and representations of the same number 367. In contrast, 0b12 and ff are neither an dInt nor an xInt.

A character is a Unicode code point, and character literals are enclosed in single quotation marks, see Appendix B.3 for a description of code points.¹ The EBNF for characters is,

```
escapeCodePoint =
  "\u" xDigit xDigit xDigit xDigit
  | "\U" xDigit xDigit xDigit xDigit xDigit xDigit xDigit xDigit
  | "\" dDigit dDigit dDigit
  escapeChar =
  "\" ("b" | "n" | "r" | "t" | "\" | """ | "a" | "f" | "v")
  | escapeCodePoint
  char = "'" codePoint | escapeChar "'"
```

where codePoint is a UTF8 encoding of a char. The escape characters escapeChar are special sequences that are interpreted as a single code point shown in Table 5.2. The trigraph \DDD uses decimal specification for the first 256 code points, and the hexadecimal escape codes \uXXXX, \UXXXXXXXX allow for the full specification of any code point. Examples of a char are 'a', '_', '\n', and '\065'. A string is a sequence of characters enclosed in double quotation marks,²

¹Spec-4.0 p.28: char-char is missing option unicodegraph-long

· bit

· binary number

 \cdot octal number

 $\begin{array}{c} \cdot \ \text{hexadecimal} \\ \text{number} \end{array}$

```
\cdot character
```

· Unicode · code point

 \cdot string

²Spec-4.0 p. 28-29: simple-string-char is undefined, string-elem is unused.

Character	Escape sequence	Description
BS	\b	Backspace
LF	\n	Newline
CR	\r	Carriage return
HT	\t	Horizontal tabulation
\	\\	Backslash
"	\"	Quotation mark
,	\'	Apostrophe
BEL	\a	Bell
FF	\f	Form feed
VT	\v	Vertical tabulation
	\uXXXX,\UXXXXXXX,\DDD	Unicode character

Table 5.2: Escape characters. For the unicode characters 'X' are hexadecimal digits, while for tricode characters 'D' is a decimal character.

```
stringChar = char - '"'
simpleString = '"' { stringChar } '"'
```

Examples are "a", "this is a string", and "-&#\@". Newlines and following white spaces are taken literally, but may be ignored by a preceding \character. Further examples of strings are,

```
> "abcde";;
val it : string = "abcde"
> "abc
- de";;
val it : string = "abc
    de"
> "abc\
- de";;
val it : string = "abcde"
> "abc\nde";;
val it : string = "abc
de"
```

Listing 5.3: fsharpi, Examples of string literals.

The response is shown in double quotation marks, which are not part of the string.

F# supports *literal types*, where the type of a literal is indicated as a prefix og suffix as shown in the — literal type Table 5.3. Examples are,

```
> 3;;
val it : int = 3
> 4u;;
val it : uint32 = 4u
> 5.6;;
val it : float = 5.6
> 7.9f;;
val it : float32 = 7.9000001f
> 'A';;
val it : char = 'A'
> 'B'B;;
val it : byte = 66uy
> "ABC";;
val it : string = "ABC"
```

Listing 5.4: fsharpi, Named and implied literals.

type	EBNF	Examples
int, int32	(dInt xInt)["1"]	3
uint32	(dInt xInt)("u" "ul")	3u
byte, uint8	((dInt xInt)"uy") (char "B")	3uy
byte[]	["@"] string "B"	"abc"B and "@http:\\"B
sbyte, int8	(dInt xInt)"y"	3у
int16	(dInt xInt)"s"	3s
uint16	(dInt xInt)"us"	3us
int64	(dInt xInt)"L"	3L
uint64	(dInt xInt)("UL" "uL")	3UL and 3uL
bignum*	dInt "I"	3I
nativeint	(dInt xInt)"n"	3n
unativeint	(dInt xInt)"un"	3un
float, double	float (xInt "LF")	3.0
single, float32	(float ("F" "f")) (xInt "lf")	3.0f
decimal	(float dInt)("M" "m")	3.0m and 3m
string	simpleString	"a \"quote\".\n"
	'@"'{(char - ('"' '\"')) '""'} '"'	@"a ""quote"".\n"
	'""' {char} '""'(*no '"""' substring*)	"""a "quote".\n"""

Table 5.3: List of literal type. No spacing is allowed between the literal and the prefix or suffix. [] notation is for lists, see Chapter 10. *bignum does not yet have an implementation for dInt ("Q"|"R "|"Z"|"N"|"G") in Mono.

Strings literals may be *verbatim* by the @-notation or tripple double quotation marks, meaning that the escape sequences are not converted to their code point., e.g.,

 $\cdot \ {\rm verbatim}$

```
> @"abc\nde";;
val it : string = "abc\nde"
```

Listing 5.5: fsharpi, Examples of a string literal.

For strings containing double quotation marks, verbatim literals has 2 possible notations, either use the @-notation and escaping double quotation marks with an extra double quotation mark, or use tripple double quotation marks. The tripple double quotation marks notation may not contain substrings that are tripple double quotation marks, and thus @-notation is preferred.

Many basic types are compatible and the type of a literal may be changed by type casting. E.g.,

Advice!

· type casting

```
> float 3;;
val it : float = 3.0
```

Listing 5.6: fsharpi, Casting an integer to a floating point number.

which is a float, since when float is given an argument, then it acts as a function rather than a type, and for the integer 3 it returns the floating point number 3.0. For more on functions see Chapter 7. Boolean values are often treated as the integer values 0 and 1, but no short-hand function names exists for their conversions. Instead use,

```
> System.Convert.ToBoolean 1;;
val it : bool = true
> System.Convert.ToBoolean 0;;
val it : bool = false
> System.Convert.ToInt32 true;;
val it : int = 1
> System.Convert.ToInt32 false;;
val it : int = 0
```

Listing 5.7: fsharpi, Casting booleans.

Here System.Convert.ToBoolean is the identifier of a function ToBoolean, which is a *member* of the *class* Convert that is included in the *namespace* System. Namespaces, classes, and members are all part of Structured programming to be discussed in Part IV.

 $\begin{array}{l} \cdot \ member \\ \cdot \ class \\ \cdot \ namespace \end{array}$

· downcasting

·upcasting

· rounding

Type casting is often a destructive operation, e.g., type casting a float to int removes the fractional part without rounding,

```
> int 357.6;;
val it : int = 357
```

Listing 5.8: fsharpi, Fractional part is removed by downcasting.

Here we type casted to a lesser type, in the sense that integers is a subset of floating point numbers, and this is called *downcasting*. The opposite is called *upcasting* and is often non-destructive, as Listing 5.6 showed, where an integer was casted to a float while retaining its value. As a side note, *rounding* a number y.x, where y is the *whole part* and x is the *fractional part*, is the operation of mapping numbers in the interval $y.x \in [y.0, y.5)$ to y and $y.x \in [y.5, y+1)$ to y+1. This can be performed by downcasting as follows,

```
y.x \in [y.0, y+1) to y+1. This can be performed by y whole part y fractional part
```

Listing 5.9: fsharpi, Fractional part is removed by downcasting.

since if $y.x \in [y.0, y.5)$, then $y.x + 0.5 \in [y.5, y + 1)$, from which downcasting removes the fractional part resulting in y. And if $y.x \in [y.5, y + 1)$, then $y.x + 0.5 \in [y + 1, y + 1.5)$, from which downcasting removes the fractional part resulting in y + 1. Hence, the result is rounding.

5.2 Operators on basic types

> int (357.6 + 0.5);;
val it : int = 358

Listing 5.9 is an example of an arithmetic expression using an infix operator. Expressions is the basic building block of all F# programs, and its grammar has many possible options. The grammar for expressions are defined recursively, and some of it is given by, 3

```
expressioninfix operator
```

```
bool = "true" | "false"
const = byte | sbyte | uint8 | int8 | int16 | uint16 | int | int32 | uint32 |
   int64 | uint64 | bignum | naviteint | unativeint | float | double | single
    | float32 | decimal | char | string | byte [] | bool | "()"
slice-range =
 expr (* single index *)
    expr ".." (* from index to end *)
   ".." expr (* from start to index *)
  | expr ".." expr (* from one index to another *)
  | "*" (* from start to end *)
expr =
 const (* constant value *)
  | "(" expr ")" (* block expression *)
  | expr operator expr (* infix operation *)
 | operator expr (* prefix operation *)
   expr expr (* function application *)
   expr ".[" slice-ranges "]" (* slice lookup *)
 1 ...
```

Recursion means that a rule or a function is used by the rule or function itself in its definition. See Part III for more on recursion. Infix notation means that the *operator* op appears between the two *operands*, and since there are 2 operands, it is a *binary operator*. As the grammar shows, the operands themselves can be expressions. Examples are 3+4 and 4+5+6. Some operators only takes one operand, e.g., -3, where - here is used to negate a postive integer. Since the operator appears before the operand it is a *prefix operator*, and since it only takes one argument it is also a *unary operator*. Finally, some

- \cdot operator

					tion

Table 5.4: Arithmetic operators on basic types. Ints, floats, chars, and strings means all built-in integer types etc.. Note that for the bitwise operations, digits 0 and 1 are taken to be true and false.

expressions are function names, which can be applied to expressions. F# supports a range of arithmetic infix and prefix operators on its built-in types shown in Table 5.4 and 5.5 and a range of mathematical functions shown in Table 5.6. Arithmetic on various types will be discussed in detail in the following sections.  4 

If parentheses are omitted in Listing 5.9, then F# will interpret the expression as (int 357.6)+ 0.5, which is erroneous, since addition of an integer with a float is undefined. This is an example of precedence, i.e., function evaluation takes precedence over addition meaning that it is performed before addition. Consider the arithmetic expression, whose result is bound to a by

```
> 3 + 4 * 5;;
val it : int = 23
```

**Listing 5.10:** fsharpi, A simple arithmetic expression.

Here, the addition and multiplication functions are shown in *infix notation* with the *operator* tokens + and *. To arrive at the resulting value 23, F# has to decide in which order to perform the calculation. There are 2 possible orders, 3 + (4 * 5) or (3 + 4) * 5, which gives different results. For integer arithmetic, the correct order is of course to multiply before addition, and we say that multiplication takes *precedence* over addition. Every atomic operation that F# can perform is ordered in terms of

&&	Left	Boolean and
11	Left	Boolean or

Table 5.7: Some common operators, their precedence, and their associativity. Rows are ordered from highest to lowest precedences, such that op * op has higher precedence than op + op. Operators in the same row has same precedence.

its precedences, and for some common built-in operators shown in Table 5.7, the precedence is shown by the order they are given in the table. Associativity implies the order in which calculations are performed for operators of same precedence. For some operators and type combinations association matters little, e.g., multiplication associates to the left and exponentiation associates to the right, e.g.,  $\sin^5$ 

```
> 3.0*4.0*5.0;;
val it : float = 60.0
> (3.0*4.0)*5.0;;
val it : float = 60.0
> 3.0*(4.0*5.0);;
val it : float = 60.0
> 4.0 ** 3.0 ** 2.0;;
val it : float = 262144.0
> (4.0 ** 3.0) ** 2.0;;
val it : float = 4096.0
> 4.0 ** (3.0 ** 2.0);;
val it : float = 262144.0
```

Listing 5.11: fsharpi, Precedences rules define implicite parentheses.

the expression for 3.0 * 4.0 * 5.0 associates to the left, and thus is interpreted as (3.0 * 4.0) * 5.0, but gives the same results as 3.0 * (4.0 * 5.0), since association does not matter for multiplication of numbers. However, the expression for 4.0 * 3.0 * 2.0 associates to the right, and thus is interpreted as 4.0 * 3.0 * 2.0, which is quite different from (4.0 * 3.0) * 2.0. Whenever in doubt of association or any other basic semantic rules, it is a good idea to use parentheses as here. It is also a good idea to test your understanding of the syntax and semantic rules by simplest possible scripts, as shown here as well.

Advice!

 $^{^5}$ Spec-4.0, Table 18.2.1 appears to be missing boolean 'and' and 'or' operations. Section 4.4 seems to be missing &&& and ||| bitwise operators.

a	b	$a \cdot b$	a+b	$\bar{a}$
0	0	0	0	1
0	1	0	1	1
1	0	0	1	0
1	1	1	1	0

Table 5.8: Truth table for boolean 'and', 'or', and 'not' operators. Value 0 is false and 1 is true.

#### 5.3 Boolean arithmetic

Boolean arithmetic is the basis of almost all computers and particularly important for controlling program flow, which will be discussed in Chapter 9. Boolean values are one of 2 possible values, true or false, which is also sometimes written as 1 and 0. Two basic operations on boolean values are 'and' often also written as multiplication, and 'or' often written as addition, and 'not' often written as a bar above the value. All possible combination of input on these values can be written on tabular form, known as a truth table, shown in Table 5.8. That is, the multiplication and addition are good mnemonics for remembering the result of the 'and' and 'or' operators. In F# the values true and false are used, and the operators && for 'and', || for 'or', and the function not for 'not', such that the above table is reproduced by,

```
> printfn "a b a*b a+b not a"
- printfn "%A %A %A %A %A"
- false false (false && false) (false || false) (not false)
- printfn "%A %A %A %A %A"
- false true (false && true) (false || true) (not false)
- printfn "%A %A %A %A %A"
- true false (true && false) (true || false) (not true)
- printfn "%A %A %A %A %A"
- true true (true && true) (true || true) (not true);;
a b a*b a+b not a
false false false false true
false true false true true
true false false true false
true true true true false
```

**Listing 5.12:** fsharpi, Boolean operators and truth tables.

Spacing produced using the printfn function is not elegant. In Section 7.2 we will discuss better options for producing more beautiful output. Notice, that the arguments for printfn was given on the next line. Here it is important to use *indentation* to indicate continuation of the line. See Section ?? for more.

 $\cdot$  indentation

## 5.4 Integer arithmetic

The set of integers is infinitely large, but since all computers have limited resources, it is not possible to represent it in their entirety. The various integer types listed in Table 5.1 are finite subset reduced by limiting their ranges. Although bignum is theoretically unlimited, the biggest number representable is still limited by computer memory. An in-depth description of integer implementation can be found in Appendix A. The type int is the most common type.

Table 5.4, 5.5, and 5.6 gives examples operators and functions pre-defined for integer types. Notice that fewer functions are available for integers than for floating point numbers. For most addition, subtraction, multiplication, and negation the result straight forward. However, performing arithmetic operations on integers requires extra care, since the result since they may cause *overflow*, *underflow*,

 $\cdot$  overflow

· underflow

e.g., the range of the integer type sbyte is [-128...127], which causes problems in the following example.

```
> 100y;;
val it : sbyte = 100y
> 30y;;
val it : sbyte = 30y
> 100y + 30y;;
val it : sbyte = -126y
```

Listing 5.13: fsharpi, Adding integers may cause overflow.

Here 100 + 30 = 130, which is larger than the biggest sbyte, and the result is an overflow. Similarly, we get an underflow, when the arithmetic result falls below the smallest value storable in an sbyte,

```
> -100y - 30y;;
val it : sbyte = 126y
```

**Listing 5.14:** fsharpi, Subtracting integers may cause underflow.

I.e., we were expecting a negative number, but got a postive number instead.

The overflow error in Listing 5.13 can be understood in terms of the binary representation of integers: In binary,  $130 = 10000010_2$ , and this binary pattern is interpreted differently as byte and sbyte,

```
> 0b10000010uy;;
val it : byte = 130uy
> 0b10000010y;;
val it : sbyte = -126y
```

Listing 5.15: fsharpi, The left most bit is interpreted differently for signed and unsigned integers, which gives rise to potential overflow errors.

That is, for signed bytes, the left-most bit is used to represent the sign, and since the addition of  $100 = 01100100_2$  and  $30 = 00011110_b$  is  $130 = 10000010_2$  causes the left-most bit to be used, then this is wrongly interpreted as a negative number, when stored in an sbyte. Similar arguments can be made explaining underflows.

The division and remainder operators *integer division*, which discards the fractional part after division, and the *remainder* operator calculates the remainder after integer division, e.g.,

 $\cdot$  integer division  $\cdot$  remainder

```
> 7 / 3;;
val it : int = 2
> 7 % 3;;
val it : int = 1
```

**Listing 5.16:** fsharpi, Integer division and remainder operators.

Together integer division and remainder is a lossless representation of the original number as,

```
> (7 / 3) * 3;;
val it : int = 6
> (7 / 3) * 3 + (7 % 3);;
val it : int = 7
```

Listing 5.17: fsharpi, Integer division and remainder is a lossless representation of an integer, compare with Listing 5.16.

And we see that integer division of 7 by 3 followed by multiplication by 3 is less that 7, and the difference is 7 % 3.

Notice that neither overflow nor underflow error gave rise to an error message, which is why such bugs are difficult to find. Dividing any non-zero number with 0 is infinite, which is also outside the domain of any of the integer types, but in this case, F# casts an *exception*,

 $\cdot \ exception$ 

```
> 3/0;;
System.DivideByZeroException: Attempted to divide by zero.
  at <StartupCode$FSI_0002>.$FSI_0002.main@ () <0x6b31288 + 0x0000e> in <
      filename unknown>:0
  at (wrapper managed-to-native) System.Reflection.MonoMethod:InternalInvoke (
      System.Reflection.MonoMethod,object,object[],System.Exception&)
  at System.Reflection.MonoMethod.Invoke (System.Object obj, BindingFlags
      invokeAttr, System.Reflection.Binder binder, System.Object[] parameters,
            System.Globalization.CultureInfo culture) <0x1a55ba0 + 0x000a1> in <
      filename unknown>:0
Stopped due to error
```

**Listing 5.18:** fsharpi, Integer division by zero causes an exception run-time error.

The output looks daunting at first sight, but the first and last line of the error message are the most important parts, which tells us what exception was cast and why the program stopped. The middle are technical details concerning which part of the program caused this, and can be ignored for the time being. Exceptions are a type of run-time error, and are treated in Chapter 11

Integer exponentiation is not defined as an operator, but this is available the built-in function pown, e.g.,

 $\cdot$  run-time error

```
> pown 2 5;;
val it : int = 32
```

**Listing 5.19:** fsharpi, Integer exponent function.

which is equal to  $2^5$ .

For binary arithmetic on integers, the following operators are available: op1 <<< op2, which shifts the bit pattern of op1 op2 positions to the left insert 0's to right; op1 >>> op2, which shifts the bit pattern of op1 op2 positions to the right insert 0's to left; op1 &&& op2, Bitwise 'and', returns the result of taking the boolean 'and' operator position-wise; op | | | op, Bitwise 'or', as 'and' but using the boolean 'or' operator; and op1 ~~~ op1, Bitwise xor, which is returns the result of the boolean 'xor' operator defined by;

a	b	a xor b
0	0	0
0	1	1
1	0	1
0	1	0

position-wise. ⁶

## 5.5 Floating point arithmetic

The set of reals is infinitely large, and since all computers have limited resources, it is not possible to represent it in their entirety. The various floating point types listed in Table 5.1 are finite subset reduced by sampling the space of reals. An in-depth description of floating point implementations can be found in Appendix A. The type float is the most common type.

Table 5.4, 5.5, and 5.6 gives examples operators and functions pre-defined for floating point types. For most addition, subtraction, multiplication, divisions, and negation the result straight forward.

The remainder operator for floats calculates the remainder after division and discarding the fractional part,

```
> 7.0 / 2.5;;
val it : float = 2.8
> 7.0 % 2.5;;
```

⁶mention somewhere that comparison operators will be treated later.

```
val it : float = 2.0
```

**Listing 5.20:** fsharpi, Floating point division and remainder operators.

The remainder for floating point numbers can be fractional, but division, discarding fractional part, and remainder is still a lossless representation of the original number as,

```
> float (int (7.0 / 2.5));;
val it : float = 2.0
> (float (int (7.0 / 2.5))) * 2.5;;
val it : float = 5.0
> (float (int (7.0 / 2.5))) * 2.5 + 7.0 % 2.5;;
val it : float = 7.0
```

Listing 5.21: fsharpi, Floating point division, truncation, and remainder is a lossless representation of a number.

Arithmetic using float will not cause over- and underflow problems, since the IEEE 754 standard includes the special numbers  $\pm \infty$  and NaN. E.g.,

```
> 1.0/0.0;;
val it : float = infinity
> 0.0/0.0;;
val it : float = nan
```

Listing 5.22: fsharpi, Floating point numbers include infinity and Not-a-Number.

However, the float type has limite precision, since there is only a finite number of numbers that can be stored in a float. E.g.,

```
> 357.8 + 0.1 - 357.9;;
val it : float = 5.684341886e-14
```

Listing 5.23: fsharpi, Floating point arithmetic has finite precision.

That is, addition and subtraction associates to the left, hence the expression is interpreted as (357.8 + 0.1) - 357.9, and we see that we do not get the expected 0, since only a limited number of floating point values are available, and the numbers 357.8 + 0.1 and 357.9 do not result in the same floating point representation. Such errors tend to accumulate and comparing the result of expressions of floating point values should therefore be treated with care. Thus, equivalence of two floating point expressions should only be considered up to sufficient precision, e.g., comparing 357.8 + 0.1 and 357.9 up to 1e-10 precission should be tested as, abs ((357.8 + 0.1) - 357.9) < 1e-10.

Advice!

## 5.6 Char and string arithmetic

Addition is the only operator defined for characters, nevertheless, character arithmetic is often done by casting to integer. A typical example is conversion of case, e.g., to convert the lowercase character 'z' to uppercase, we use the *ASCIIbetical order* and add the difference between any Basic Latin Block letters in upper- and lowercase as integers and cast back to char, e.g.,

· ASCIIbetical order

```
> char (int 'z' - int 'a' + int 'A');;
val it : char = 'Z'
```

**Listing 5.24:** fsharpi, Converting case by casting and integer arithmetic.

I.e., the code point difference between upper and lower case for any alphabetical character 'a' to 'z' is constant, hence we can change case by adding or subtracting the difference between any corresponding character. Unfortunately, this does not generalize to characters from other languages.

A large collection of operators and functions exist for string. The most simple is concatenation using, e.g.,

```
> "hello" + " " + "world";;
val it : string = "hello world"
```

Listing 5.25: fsharpi, Example of string concatenation.

Characters and strings cannot be concatenated, which is why the above example used the string of a space " " instead of the space character ' '. The characters of a string may be indexed as,

```
> "abcdefg".[0];;
val it : char = 'a'
> "abcdefg".[3];;
val it : char = 'd'
> "abcdefg".[3..];;
val it : string = "defg"
> "abcdefg".[..3];;
val it : string = "abcd"
> "abcdefg".[1..3];;
val it : string = "bcd"
> "abcdefg".[*];;
val it : string = "abcdefg"
```

Listing 5.26: fsharpi, String indexing using square brackets.

Notice, that the first character has index 0, and to get the last character in a string, we use the string's length property as,

```
> "abcdefg".Length;;
val it : int = 7
> "abcdefg".[7-1];;
val it : char = 'g'
```

Listing 5.27: fsharpi, String length attribute and string indexing.

Notice, since index counting starts at 0, and the string length is 7, then the index of the last character is 6. An alternative notation for indexing is to use the property Char, and in the example ''abcdefg''. [3] is the same as a.Char 3. The is a long list of built-in functions in System.String for working with strings, some of which will be discussed in Chapter 15.1.

The *dot notation* is an example of Structured programming, where technically speaking, the string "abcdefg" is an immutable *object* of *class* string, and [] is an object *method* and Length is a property. For more on object, classes, and methods see Chapter 18.

#### · dot notation

- · object
- · class
- $\cdot$  method

#### 5.7 Unit of Measure

F# allows for assigning unit of measure to the following types,

· unit of measure

sbyte, int, int16, int32, int64, single, float32, float, and decimal.

by using the syntax,

```
"[<Measure>] type" unit-name [ "=" measure ]
```

and then use "<" unit-name ">" as suffix for literals. In Figure ??

E.g., defining unit of measure 'm' and 's', then we can make calculations like,

```
> [<Measure>] type m
- [<Measure>] type s
- let a = 3<m/s^2>
- let b = a * 10<s>
- let c = 4 * b;;
```

```
[<Measure>]
type m
[<Measure>]
type s
val a : int<m/s ^ 2> = 3
val b : int<m/s> = 30
val c : int<m/s> = 120
```

Listing 5.28: fsharpi, floating point and integer numbers may be assigned unit of measures.

However, if we mixup unit of measures under addition, then we get an error,

Listing 5.29: fsharpi, unit of measures adds an extra layer of types for syntax checking at compile time.

Unit of measures allow for *, /, and  7  for multiplication, division and exponentiation. Values with units can be casted to *unit-less* values by casting, and back again by multiplication as,

· unit-less

```
> [<Measure>] type m
- let a = 2<m>
- let b = int a
- let c = b * 1<m>;;

[<Measure>]
type m
val a : int<m> = 2
val b : int = 2
val c : int<m> = 2
```

**Listing 5.30:** fsharpi, type casting unit of measures.

Compound symbols can be declared as,

```
> [<Measure>] type s
- [<Measure>] type m
- [<Measure>] type kg
- [<Measure>] type N = kg * m / s^2;;

[<Measure>]
type s
[<Measure>]
type m
[<Measure>]
type kg
[<Measure>]
type kg
[<Measure>]
type kg
[<Measure>]
type kg
```

Listing 5.31: fsharpi, aggregated unit of measures.

For fans of the metric system there is the International System of Units, and these are built-in in Microsoft.FSharp.Data.UnitSystems.SI.UnitSymbols and give in Table 5.9. Hence, using the

⁷Spec-4.0: this notation is inconsistent with ** for float exponentiation.

Unit	Description
A	Ampere, unit of electric current.
Bq	Becquerel, unit of radioactivity.
C	Coulomb, unit of electric charge, amount of electricity.
cd	Candela, unit of luminous intensity.
F	Farad, unit of capacitance.
Gy	Gray, unit of an absorbed dose of radiation.
H	Henry, unit of inductance.
Hz	Hertz, unit of frequency.
J	Joule, unit of energy, work, amount of heat.
K	Kelvin, unit of thermodynamic (absolute) temperature.
kat	Katal, unit of catalytic activity.
kg	Kilogram, unit of mass.
lm	Lumen, unit of luminous flux.
lx	Lux, unit of illuminance.
m	Metre, unit of length.
mol	Mole, unit of an amount of a substance.
N	Newton, unit of force.
ohm	Unitnames.o SI unit of electric resistance.
Pa	Pascal, unit of pressure, stress.
s	Second, unit of time.
S	Siemens, unit of electric conductance.
Sv	Sievert, unit of dose equivalent.
T	Tesla, unit of magnetic flux density.
V	Volt, unit of electric potential difference, electromotive force.
W	Watt, unit of power, radiant flux.
Wb	Weber, unit of magnetic flux.

Table 5.9: International System of Units.

predefined unit of seconds, we may write,

```
> let a = 10.0 < Microsoft.FSharp.Data.UnitSystems.SI.UnitSymbols.s>;;
val a : float < Data.UnitSystems.SI.UnitSymbols.s> = 10.0
```

Listing 5.32: fsharpi, SI unit of measures are built-in.

To make the use of these predefined symbols easier, we can import them into the present scope by the open keyword,

```
·open
```

```
> open Microsoft.FSharp.Data.UnitSystems.SI.UnitSymbols;;
> let a = 10.0<s>;;
val a: float<s> = 10.0
```

Listing 5.33: fsharpi, simpler syntax by importing, but beware of namespace pollution.

The open keyword should be used with care, since now all the bindings in Microsoft.FSharp. Data.UnitSystems.SI.UnitSymbols have been imported into the present scope, and since we most likely do not know, which bindings have been used by the programmers of Microsoft.FSharp.Data.UnitSystems.SI.UnitSymbols, we do not know which identifiers to avoid, when using let statements. We have obtained, what is known as namespace pollution. Read more about namespaces in Part IV. Using unit of measures is advisable for calculations involving real-world values, since some semantical errors of arithmetic expressions may be discovered by checking the resulting unit of measure.

 $\begin{array}{c} \cdot \ name space \\ pollution \end{array}$ 

⁸add comparison operators!

## Chapter 6

## Identifiers, functions, and variables

An identifier is bound to an expression by the syntax,

```
"let" [ "mutable" ] ident [":" type] "=" expr ["in" expr]
```

·let

·in

·in

· literal

That is, the *let* keyword indicates that the following is a binding of an identifier with an expression, and that the type may be specified with the : token. An identifier must start with a letter, but can be followed by zero or more of letters, digits, and a range of special characters. For characters in the Basic Latin Block, i.e., the first 128 code points alias ASCII characters, an ident is,

```
digit = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9"
letter = "A" | "B" | ... | "Z" | "a" | "b" | ... | "z"
special-char = "_"
ident = (letter | "_") {letter | digit | special-char}
```

Thus, examples of identifiers are a, the Character 9, Next_Word, _tok. The for the full definition, letter = Lu | Ll | Lt | Lm | Lo | Nl and special-char = Pc | Mn | Mc | Cf, which referes to the Unicode general categories described in Appendix B.3, and there are currently 19.345 possible Unicode code points in the letter category and 2.245 possible Unicode code points in the special -char category. An identifier must not be a keyword or a reserved-keyword, shown in Figure 6.1 and 6.2. The binding may be mutable, which will be discussed in Section 6.2, and the binding may only be for the last expression as indicated by the *in* keyword. The simplest example of an expression is a *literal*, i.e., a constant such as the number 3.

A less common notation is to define bindings for expressions using the *in* keyword, e.g.,

```
let p = 2.0 in printfn "%A" (3.0 ** p)
```

```
9.0
```

Listing 6.1: numbersIn.fsx - The identifier **p** is only bound in the nested scope following the keyword in.

Here **p** is only bound in the *scope* of the expression following the **in** keyword, in this the **printfn** · scope statement, and **p** is unbound in lines that follows.

abstract, and, as, assert, base, begin, class, default, delegate, do, done, downcast, downto, elif, else, end, exception, extern, false, finally, for, fun, function, global, if, in, inherit, inline, interface, internal, lazy, let, match, member, module, mutable, namespace, new, null, of, open, or, override, private, public, rec, return, sig, static, struct, then, to, true, try, type, upcast, use, val, void, when, while, with, and yield.

Figure 6.1: List of keywords in F#.

atomic, break, checked, component, const, constraint, constructor, continue, eager, fixed, fori, functor, include, measure, method, mixin, object, parallel, params, process, protected, pure, recursive, sealed, tailcall, trait, virtual, and volatile.

Figure 6.2: List of reserved keywords for possible future use in F#.

### 6.1 Values (Constant bindings)

When specifying the type, the type and the literal form must match, i.e., mixing types and literals gives an error,

```
> let a : float = 3;;
let a : float = 3;;
-----
/Users/sporring/repositories/fsharpNotes/stdin(50,17): error FS0001: This expression was expected to have type float
but here has type int
```

**Listing 6.2:** fsharpi, binding error due to type mismatch.

since the left-hand-side is an identifier of type float, while the right-hand-side is a literal of type integer.

## 6.2 Variables (Mutable bindings)

The mutable in let bindings means that the identifier may be rebound to a new value using the following syntax,

```
ident "<-" expr
```

Mutable data is synonymous with the term variable. A variable is an area in the computers working memory associated with an identifier and a type, and this area may be read from and written to during program execution. For example,

· Mutable data · variable

```
let mutable x = 5
printfn "%d" x
x <- -3
printfn "%d" x</pre>
```

```
5
-3
```

Listing 6.3: mutableAssignReassingShort.fsx - A variable is defined and later reassigned a new value.

Here a area in memory was denoted x, initially assigned the integer value 5, hence the type was inferred to be int. Later, this value of x was replaced with another integer using the <- token. The <- token · is used to distinguish the assignment from the comparison operator, i.e., if we by mistake had written,

```
> let mutable a = 0
- a = 3;;

val mutable a : int = 0
val it : bool = false
```

Listing 6.4: fsharpi, example of changing the content of a variable.

then we instead would have obtained the default assignment of the result of the comparision of the content of a with the integer 3, which is false. However, it's important to note, that when the variable is initially defined, then the '|=|' operator must be used, while later reassignments must use the |<-| operator.

Assignment type mismatches will result in an error,

```
let mutable x = 5
printfn "%d" x
x <- -3.0
printfn "%d" x</pre>
```

```
/Users/sporring/repositories/fsharpNotes/src/mutableAssignReassingTypeError.
fsx(3,6): error FS0001: This expression was expected to have type
int
but here has type
float
```

Listing 6.5: mutableAssignReassingTypeError.fsx - Assignment type mismatching causes a compile time error.

I.e., once the type of an identifier has been declared or inferred, then it cannot be changed. A typical variable is a counter of type integer, and a typical use of counters is to increment them, i.e., erasing a new value to be one more that its previous value. For example,

```
let mutable x = 5 // Declare a variable x and assign the value 5 to it printfn "%d" x x <- x + 1 // Assign a new value -3 to x printfn "%d" x
```

```
5
6
```

Listing 6.6: mutableAssignIncrement.fsx - Variable increment is a common use of variables.

which is an example we will return to many times later in this text.

2

. . .

¹Somewhere I should talk about whitespaces and newlines Spec-4.0 Chapter 3.1

²Somewhere I should possibly talk about Lightweight Syntax, Spec-4.0 Chapter 15.1

## Chapter 7

# Functions and procedures (function bindings)

Function definition follows the same syntax as literal binding,

```
"let" ["rec"] ident valIdent {valIdent} [":" type] "=" expr ["in" expr] valident = ident | "(" ident ":" type ")"
```

or specify the type of the function at point of definition using the notation,

```
"let" name argWType { argWType } [ ":" type ] "=" expr
argWType = arg | "(" arg ":" type ")"
```

where not all types need to be declared, just sufficent for F# to be able to infer the types for the full statement. In the example, one sufficent specification is,

```
> let sum (x : float) (y : float) = x + y;;
val sum : x:float -> y:float -> float
> let c = sum 357.6 863.4;;
val c : float = 1221.0
```

Listing 7.1: fsharpi

but alternatively we could have specified the type of the result,

```
let sum x y : float = x + y
```

or even just one of the arguments,

```
let sum (x : float) y = x + y
```

In both cases, since the + operator is only defined for operands of the same type, then when the type of either the result, any or both operands are declared, then the type of the remaining follows directly. A function that elegantly implements the incrementation operation may be constructed as,

 $\cdot$  operator

 $\cdot$  operand

```
let incr =
  let mutable counter = 0
  fun () ->
    counter <- counter + 1
    counter
printfn "%d" (incr ())
printfn "%d" (incr ())
printfn "%d" (incr ())</pre>
```

```
1
2
3
```

**Listing 7.2:** mutableAssignIncrementEncapsulation.fsx -

¹ Here the output of incr is an anonymous function, that takes no argument, increments the variable of incr and returns the new value of the counter. This construction is called *encapsulation*, since the variable counter is hidden by the function incr from the user, i.e., the user need not be concerned with how the increment operator is implemented and the variable name used by incr does not clutter the scope where it is used.

 $\cdot$  encapsulation

Variables cannot be returned from functions, that is,

```
let g () =
  let x = 0
  x
printfn "%d" (g ())
```

```
0
```

**Listing 7.3:** mutableAssignReturnValue.fsx -

declares a function that has no arguments and returns the value 0, while the same for a variable is illegal,

```
let g () =
  let mutual x = 0
  x
printfn "%d" (g ())
```

```
/Users/sporring/repositories/fsharpNotes/src/mutableAssignReturnVariable.fsx (3,3): error FS0039: The value or constructor 'x' is not defined
```

**Listing 7.4:** mutableAssignReturnVariable.fsx -

There is a workaround for this by using reference cells by the build-in function ref and operators |!| · reference cells and |:=|,

```
let g () =
  let x = ref 0
  x
let y = g ()
  printfn "%d" !y
y := 3
printfn "%d" !y
```

```
0
3
```

**Listing 7.5:** mutableAssignReturnRefCell.fsx -

That is, the ref function creates a reference variable, the '|!|' and the '|:=|' operators reads and writes its value. Reference cells are in some language called pointers, and their use is strongly discouraged, since they may cause *side-effects*, which is the effect that one function changes the state of another, such as the following example demonstrates,

 $\cdot \, side\text{-effects}$ 

¹Explain why this works!

```
let updateFactor factor =
  factor := 2

let multiplyWithFactor x =
  let a = ref 1
  updateFactor a
  !a * x

printfn "%d" (multiplyWithFactor 3)
```

```
6
```

Listing 7.6: mutableAssignReturnSideEffect.fsx -

In the example, the function updateFactor changes a variable in the scope of multiplyWithFactor, which is prone to errors, since the style of programming does not follow the usual assignment syntax. Better style of programming is,

```
let updateFactor () =
  2

let multiplyWithFactor x =
  let a = ref 1
  a := updateFactor ()
  !a * x

printfn "%d" (multiplyWithFactor 3)
```

```
6
```

**Listing 7.7:** mutableAssignReturnWithoutSideEffect.fsx -

Here there can be no doubt in multiplyWithFactor that the value of 'a' is changing. Side-effects do have their use, but should in general be avoided at almost all costs, and in general it is advised to refrain from using ref cells.

A function is a mapping between an input and output domain. F# is a functional first programming language, and offers a number of alternative methods for specifying parameters. A simple example is,

```
let mul (x, y) = x*y
let z = mul (3, 5)
printfn "%d" z
```

```
15
```

Listing 7.8: functionDeclarationMul.fsx -

which declares a function of a tuple and returns their multiplication. The types are inferred from its first use in the second line, i.e., mul is val mul: x:int * y:int -> int. An argument may be of generic type for input, which need not be inferred without sacrificing type safety, e.g.,

```
let second (x, y) = y
let a = second (3, 5)
printfn "%A" a
let b = second ("horse", 5.0)
printfn "%A" b
```

```
5
5.0
```

**Listing 7.9:** functionDeclarationGeneric.fsx -

Here the function **second** does not use the first element in the tuple, x, and the type of the second element, y, can safely be anything.

Functions may be anonymously declared using the fun keyword,

```
let first = fun (x, y) -> x
printfn "%d" (first (5, 3))
```

```
5
```

Listing 7.10: functionDeclarationAnonymous.fsx -

Anonymous functions are often used as arguments to other functions, e.g.,

```
let apply (f, x, y) = f (x, y)
let z = apply ((fun (a, b) -> a * b), 3, 6)
printfn "%d" z
```

```
18
```

Listing 7.11: functionDeclarationAnonymousAdvanced.fsx -

This is a powerfull concept, but can make programs hard to read, and overly use is not recommended. Functions may be declared using pattern matching, which is a flexible method for declaring output depending on conditions on the input value. The most common pattern matching method is by use of the match with syntax,

```
let rec factorial n =
    match n with
    | 0 -> 1
    | 1 -> 1
    | _ -> n * (factorial (n - 1))
printfn "%d" (factorial 5)
```

```
120
```

**Listing 7.12:** functionDeclarationMatchWith.fsx -

A short-hand only for functions of 1 parameter is the function syntax,

```
120
```

**Listing 7.13:** functionDeclarationFunction.fsx -

Note that the name given in the match, here n, is not used in the first line, and is arbitrary at the line of pattern matchin, and may even be different on each line. For these reasons is this syntax discouraged. Functions may be declared from other functions

```
let mul (x, y) = x*y
let double y = mul (2.0, y)
printfn "%g" (mul (5.0, 3.0))
printfn "%g" (double 3.0)
```

```
15
6
```

**Listing 7.14:** functionDeclarationTupleCurrying.fsx -

For functions of more than 1 argument, there exists a short notation, which is called *currying* in tribute · currying of Haskell Curry,

```
let mul x y = x*y
let double = mul 2.0
printfn "%g" (mul 5.0 3.0)
printfn "%g" (double 3.0)
```

```
15
6
```

**Listing 7.15:** functionDeclarationCurrying.fsx -

Here mul 2.0 is a partial specification of the function mul x y, where the first argument is fixed, and hence, double is a function of 1 argument being the second argument of mul. Currying is often used in functional programming, but generally currying should be used carefully, since currying may seriously reduce readability of code.

#### 7.1 Procedures

A procedure is a generalisation of the concept of functions, and in contrast to functions procedures need not return values. An example, we've already seen is the printfn, which is used to print text on the console, but does not return a value. Coincidentally, since the console is a state, printing to it is a side-effect. Above we examined

· procedure

```
let updateFactor factor =
  factor := 2
```

which also does not have a return value. Procedural thinking is useful for encapsulation, but is prone to side-effects and should be minimized by being replaced by functional thinking.

#### 7.2 Printf

2

 $^{^2}$ Maybe explain the printf function, Spec-4.0 Section 6.3.16 'printf' Formats, but also max and min comparison functions and math functions Section 18.2.2 and 18.2.4?

## Chapter 3

# A brief introduction to Extended Backus-Naur Form

digit = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9" ;

Extended Backus-Naur Form (EBNF) is a language to specify programming languages in. The name is a tribute to John Backus who used it to describe the syntax of ALGOL58 and Peter Nauer for his work on ALGOL 60.

· Extended Backus-Naur Form

An EBNF consists of terminal symbols and production rules. Examples of typical terminal symbol are characters, numbers, punctuation marks, and whitespaces, e.g.,

```
\cdot EBNF
```

- · terminal symbols

 $\cdot$  production rules

```
A production rule specifies a method of combining other production rules and terminal symbols, e.g., number = { digit } ;
```

A proposed standard for EBNF (proposal ISO/IEC 14977, http://www.cl.cam.ac.uk/~mgk25/iso-14977.pdf) is,

'=' definition, e.g.,

```
zero = "0" ;
```

here  ${\tt zero}$  is the terminal symbol 0.

',' concatenation, e.g.,

```
one = "1" ;
eleven = one, one ;
```

here eleven is the terminal symbol 11.

- ';' termination of line
- '|' alternative options, e.g.,

```
digit = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9" ;
```

here digit is the single character terminal symbol, such as 3.

'[ ... ]' optional, e.g.,

```
zero = "0";
nonZeroDigit = "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
nonZero = [ zero ], nonZeroDigit
```

here nonZero is a non-zero digit possibly preceded by zero, such as 02.

'{ ...}' repetition zero or more times, e.g.,

```
digit = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
number = digit, { digit }
```

here number is a word consisting of 1 or more digits, such as 12.

'(  $\dots$  )' grouping, e.g.,

```
digit = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
number = digit, { digit }
expression = number, { ( "+" | "-" ), number };
```

here expression is a number or a sum of numbers such as 3 + 5.

" ... " a terminal string, e.g.,

```
string = "abc"';
```

"' ... '" a terminal string, e.g.,

```
string = 'abc';
```

'(* ... *)' a comment (* ... *)

```
(* a binary digit *) digit = "0" | "1" (* from this all numbers may be
  constructed *);
```

Everything inside the comments are not part of the formal definition.

'? ... ?' special sequence, a notation reserved for future extensions of EBNF.

'-' exception, e.g.,

here consonant are all letters except vowels.

The proposal allows for identifies that includes space, but often a reduced form is used, where identifiers are single words, in which case the concatenation symbol , is omitted. Likewise, the termination symbol ; is often replaced with the new-line character, and if long lines must be broken, then indentation is used to signify continuation.

In this relaxed EBNF, the EBNF syntax itself can be expressed in EBNF as,

```
string = character { character }
terminal = "'" string "'" | '"" string '""

rhs = identifier
    | terminal
    | "[" rhs "]"
    | "(" rhs ")"
    | rhs "|" rhs
    (* | rhs "," rhs *)
rule = identifier "=" rhs (* ";" *)
grammar = rule { rule }
```

Here the comments demonstrate, the relaxed modification.
